

Thank you for your purchase of the Raven from Stami's Customs!

Here are some basic operating instructions and hook up guide.

The Raven is a very simple circuit consisting of a 100w (RMS) 200w (peak) rated L-Pad and a 500V ZoSo coupling capacitor to pass high frequencies around the L-Pad when attenuating. As we know tube amplifier ratings can vary based on actual output tubes used, transformer ratings, and even wall voltage. That being said, I have conservatively rated these @ 65 Watts to allow for headroom and proper cooling. The Raven will get fairly HOT especially after hours of playing so be careful to let it cool before moving it.

Proper hook up: Holding the Raven with the attenuation knob at the bottom and the input/output jacks toward the top, the left jack always goes to the amplifier while the right jack connects directly to the speaker. Always use Speaker cable of 16GA or larger for the amp connection.

From Amplifier

To Speaker

IMPORTANT! - Make sure your amplifier is rated for Ohm output. If it is not, do not use. sAs this could cause damage to your amplifiers output transformer. You have been warned! I will not accept responsibly for improper use or hook up. Use with amplifiers rated over 65 Watts is at your own risk!
